

## Scalar Data Types Booleans

The Boolean Data Type is a data type, having two values (usually denoted true or false), intended to represent the truth values of logic and Boolean Algebra.

Specification :- In Pascal and Ada, the Boolean datatype is considered simply a language-defined enumeration, viz;

`type Boolean = (false, true);`

which both defines the names true and false for the values of the types and defines ordering `false < true`.

Common operations are

And : Boolean  $\times$  Boolean  $\rightarrow$  Boolean (Conjunction)

Or : Boolean  $\times$  Boolean  $\rightarrow$  Boolean (inclusive disjunction)

not : Boolean  $\rightarrow$  Boolean. (negative or Complement)

### Implementation :-

Single bit of storage is provided, no descriptor designated the data type is needed. Because single bits may not be separately addressable in memory which often takes a byte or word to represent it if extended.

Then the values true and false might be represented

in two ways within this storage unit :

- ① A particular bit is used for the value (often the sign bit of the number representation), with  $0 = \text{false}$ ,  $1 = \text{true}$ , and the rest of the byte or word ignored, or
- ② A zero value in the entire storage unit represents false, and any other nonzero value represents true.

1)

0	1	0	0	1	0	1	0
---	---	---	---	---	---	---	---

if this is particular  
bit which is to be  
considered  
 $0 = \text{false}$   
 $1 = \text{true}$

Ignored

2)

0	0	0	0	0	0	0	0
---	---	---	---	---	---	---	---

$0 = \text{false}$   
 $1 = \text{true}$

1	1	1	1	1	1	1	1
---	---	---	---	---	---	---	---
